Expanding brackets and simplifying expressions

A LEVEL LINKS

Scheme of work: 1a. Algebraic expressions – basic algebraic manipulation, indices and surds

Key points

- When you expand one set of brackets you must multiply everything inside the bracket by what is outside.
- When you expand two linear expressions, each with two terms of the form ax + b, where $a \ne 0$ and $b \ne 0$, you create four terms. Two of these can usually be simplified by collecting like terms

Examples

Example 1 Expand 4(3x - 2)

4(3x - 2) = 12x - 8	Multiply everything inside the bracket by the 4 outside the bracket
---------------------	---

Example 2 Expand and simplify 3(x+5) - 4(2x+3)

$$3(x+5) - 4(2x+3)$$

$$= 3x + 15 - 8x - 12$$

$$= 3 - 5x$$
1 Expand each set of brackets separately by multiplying $(x + 5)$ by 3 and $(2x + 3)$ by -4
2 Simplify by collecting like terms: $3x - 8x = -5x$ and $15 - 12 = 3$

Example 3 Expand and simplify (x + 3)(x + 2)

$$(x+3)(x+2)$$

$$= x(x+2) + 3(x+2)$$

$$= x^2 + 2x + 3x + 6$$

$$= x^2 + 5x + 6$$
1 Expand the brackets by multiplying $(x+2)$ by x and $(x+2)$ by x and x are x and x are x and x are x and x are x are x and x are x are x and x are x and x are x are x and x are x are x and x are x and x and x are x are x and x are x and x are x and x are x are x and x are x are x and x are x and x are x are x are x and x are x are x and x are x and x are x are x and x are x and x are x and x are x are x are x and x are x are x are x are x are x and x are x are x and x are x and x are x are x and x are x are x and x are x

Example 4 Expand and simplify (x-5)(2x+3)

$$(x-5)(2x+3)$$

= $x(2x+3)-5(2x+3)$
= $2x^2+3x-10x-15$
= $2x^2-7x-15$
1 Expand the brackets by multiplying $(2x+3)$ by x and $(2x+3)$ by -5
2 Simplify by collecting like terms: $3x-10x=-7x$

Rearranging equations

A LEVEL LINKS

Scheme of work: 6a. Definition, differentiating polynomials, second derivatives

Textbook: Pure Year 1, 12.1 Gradients of curves

Key points

- To change the subject of a formula, get the terms containing the subject on one side and everything else on the other side.
- You may need to factorise the terms containing the new subject.

Examples

Example 1 Make *t* the subject of the formula v = u + at.

v = u + at $v - u = at$	1 Get the terms containing <i>t</i> on one side and everything else on the other side.
$t = \frac{v - u}{a}$	2 Divide throughout by <i>a</i> .

Example 2 Make t the subject of the formula $r = 2t - \pi t$.

$r = 2t - \pi t$	1 All the terms containing <i>t</i> are already on one side and everything
$r = t(2 - \pi)$	else is on the other side. 2 Factorise as <i>t</i> is a common factor.
$t = \frac{r}{2 - \pi}$	3 Divide throughout by $2 - \pi$.

Example 3 Make *t* the subject of the formula $\frac{t+r}{5} = \frac{3t}{2}$.

$\frac{t+r}{5} = \frac{3t}{2}$	1 Remove the fractions first by multiplying throughout by 10.
2t + 2r = 15t	2 Get the terms containing <i>t</i> on one side and everything else on the other
2r = 13t	side and simplify.
$t = \frac{2r}{13}$	3 Divide throughout by 13.

$$r = \frac{3t+5}{t-1}$$

$$r(t-1) = 3t+5$$

$$rt - r = 3t+5$$

$$rt - 3t = 5 + r$$

$$t(r-3) = 5 + r$$

$$r(t-1) = 3t + 5$$

$$rt - r = 3t + 5$$

$$rt - 3t = 5 + r$$

$$t(r-3) = 5 + r$$

$$t = \frac{5+r}{r-3}$$

- 1 Remove the fraction first by multiplying throughout by t - 1.
- 2 Expand the brackets.
- 3 Get the terms containing t on one side and everything else on the other
- Factorise the LHS as t is a common factor.
- 5 Divide throughout by r 3.

Factorising expressions

A LEVEL LINKS

Scheme of work: 1b. Quadratic functions – factorising, solving, graphs and the discriminants

Key points

- Factorising an expression is the opposite of expanding the brackets.
- A quadratic expression is in the form $ax^2 + bx + c$, where $a \ne 0$.
- To factorise a quadratic equation find two numbers whose sum is b and whose product is ac.
- An expression in the form $x^2 y^2$ is called the difference of two squares. It factorises to (x y)(x + y).

Examples

Example 1 Factorise $15x^2y^3 + 9x^4y$

$15x^2y^3 + 9x^4y = 3x^2y(5y^2 + 3x^2)$	The highest common factor is $3x^2y$. So take $3x^2y$ outside the brackets and then divide each term by $3x^2y$ to find the terms in the brackets
---	---

Example 2 Factorise $4x^2 - 25y^2$

$4x^2 - 25y^2 = (2x + 5y)(2x - 5y)$	This is the difference of two squares as the two terms can be written as $(2x)^2$ and $(5y)^2$
-------------------------------------	--

Example 3 Factorise $x^2 + 3x - 10$

b = 3, ac = -10	1 Work out the two factors of $ac = -10$ which add to give $b = 3$ (5 and -2)
So $x^2 + 3x - 10 = x^2 + 5x - 2x - 10$	2 Rewrite the <i>b</i> term (3 <i>x</i>) using these two factors
= x(x+5) - 2(x+5)	3 Factorise the first two terms and the last two terms
=(x+5)(x-2)	4 $(x + 5)$ is a factor of both terms

Example 4 Factorise $6x^2 - 11x - 10$

$$b = -11, ac = -60$$
So
$$6x^{2} - 11x - 10 = 6x^{2} - 15x + 4x - 10$$

$$= 3x(2x - 5) + 2(2x - 5)$$

$$= (2x - 5)(3x + 2)$$

- 1 Work out the two factors of ac = -60 which add to give b = -11 (-15 and 4)
- 2 Rewrite the *b* term (-11x) using these two factors
- 3 Factorise the first two terms and the last two terms
- 4 (2x-5) is a factor of both terms

Example 5 Simplify $\frac{x^2 - 4x - 21}{2x^2 + 9x + 9}$

$$\frac{x^2 - 4x - 21}{2x^2 + 9x + 9}$$

For the numerator: b = -4, ac = -21

So

$$x^2 - 4x - 21 = x^2 - 7x + 3x - 21$$

 $= x(x - 7) + 3(x - 7)$
 $= (x - 7)(x + 3)$

For the denominator: b = 9, ac = 18

$$= 2x(x+3) + 3(x+3)$$

$$= (x+3)(2x+3)$$
So
$$\frac{x^2 - 4x - 21}{2x^2 + 9x + 9} = \frac{(x-7)(x+3)}{(x+3)(2x+3)}$$

$$= \frac{x-7}{2x+3}$$

 $2x^2 + 9x + 9 = 2x^2 + 6x + 3x + 9$

- 1 Factorise the numerator and the denominator
- 2 Work out the two factors of ac = -21 which add to give b = -4 (-7 and 3)
- 3 Rewrite the b term (-4x) using these two factors
- **4** Factorise the first two terms and the last two terms
- 5 (x-7) is a factor of both terms
- 6 Work out the two factors of ac = 18 which add to give b = 9 (6 and 3)
- 7 Rewrite the b term (9x) using these two factors
- **8** Factorise the first two terms and the last two terms
- 9 (x + 3) is a factor of both terms
- **10** (*x* + 3) is a factor of both the numerator and denominator so cancels out as a value divided by itself is 1

Completing the square

A LEVEL LINKS

Scheme of work: 1b. Quadratic functions – factorising, solving, graphs and the discriminants

Key points

- Completing the square for a quadratic rearranges $ax^2 + bx + c$ into the form $p(x + q)^2 + r$
- If $a \ne 1$, then factorise using a as a common factor.

Examples

Example 1 Complete the square for the quadratic expression $x^2 + 6x - 2$

Solving quadratic equations by factorisation

A LEVEL LINKS

Scheme of work: 1b. Quadratic functions – factorising, solving, graphs and the discriminants

Key points

- A quadratic equation is an equation in the form $ax^2 + bx + c = 0$ where $a \ne 0$.
- To factorise a quadratic equation find two numbers whose sum is *b* and whose products is
- When the product of two numbers is 0, then at least one of the numbers must be 0.
- If a quadratic can be solved it will have two solutions (these may be equal).

Examples

Example 1 Solve $5x^2 = 15x$

$5x^2 = 15x$	1 Rearrange the equation so that all of
$5x^2 - 15x = 0$	the terms are on one side of the equation and it is equal to zero.
	Do not divide both sides by x as this would lose the solution $x = 0$.
5x(x-3)=0	2 Factorise the quadratic equation. 5x is a common factor.
So $5x = 0$ or $(x - 3) = 0$	3 When two values multiply to make
	zero, at least one of the values must be zero.
Therefore $x = 0$ or $x = 3$	4 Solve these two equations.

Example 2 Solve $x^2 + 7x + 12 = 0$

$x^2 + 7x + 12 = 0$	1 Factorise the quadratic equation.
b = 7, ac = 12	Work out the two factors of $ac = 12$ which add to give you $b = 7$. (4 and 3)
$x^2 + 4x + 3x + 12 = 0$	2 Rewrite the <i>b</i> term (7 <i>x</i>) using these two factors.
x(x+4) + 3(x+4) = 0	3 Factorise the first two terms and the last two terms.
(x+4)(x+3)=0	4 $(x + 4)$ is a factor of both terms.
So $(x + 4) = 0$ or $(x + 3) = 0$	5 When two values multiply to make zero, at least one of the values must be zero.
Therefore $x = -4$ or $x = -3$	6 Solve these two equations.

Example 3 Solve $9x^2 - 16 = 0$

$$9x^2 - 16 = 0$$
$$(3x + 4)(3x - 4) = 0$$

So
$$(3x + 4) = 0$$
 or $(3x - 4) = 0$

$$x = -\frac{4}{3}$$
 or $x = \frac{4}{3}$

- 1 Factorise the quadratic equation. This is the difference of two squares as the two terms are $(3x)^2$ and $(4)^2$.
- 2 When two values multiply to make zero, at least one of the values must be zero.
- 3 Solve these two equations.

Example 4 Solve $2x^2 - 5x - 12 = 0$

$$b = -5$$
, $ac = -24$

So
$$2x^2 - 8x + 3x - 12 = 0$$

$$2x(x-4) + 3(x-4) = 0$$

$$(x-4)(2x+3)=0$$

So
$$(x-4) = 0$$
 or $(2x+3) = 0$

$$x = 4$$
 or $x = -\frac{3}{2}$

- 1 Factorise the quadratic equation. Work out the two factors of ac = -24 which add to give you b = -5. (-8 and 3)
- 2 Rewrite the *b* term (-5x) using these two factors.
- **3** Factorise the first two terms and the last two terms.
- 4 (x-4) is a factor of both terms.
- 5 When two values multiply to make zero, at least one of the values must be zero.
- **6** Solve these two equations.

Solving quadratic equations by completing the square

A LEVEL LINKS

Scheme of work: 1b. Quadratic functions – factorising, solving, graphs and the discriminants

Key points

• Completing the square lets you write a quadratic equation in the form $p(x+q)^2 + r = 0$.

Examples

Example 5 Solve $x^2 + 6x + 4 = 0$. Give your solutions in surd form.

$$x^{2} + 6x + 4 = 0$$

$$(x+3)^{2} - 9 + 4 = 0$$

$$(x+3)^{2} - 5 = 0$$

$$(x+3)^{2} = 5$$

$$x+3 = \pm\sqrt{5}$$

$$x = \pm\sqrt{5} - 3$$
So $x = -\sqrt{5} - 3$ or $x = \sqrt{5} - 3$

- 1 Write $x^2 + bx + c = 0$ in the form $\left(x + \frac{b}{2}\right)^2 \left(\frac{b}{2}\right)^2 + c = 0$
- 2 Simplify.
- 3 Rearrange the equation to work out *x*. First, add 5 to both sides.
- 4 Square root both sides. Remember that the square root of a value gives two answers.
- 5 Subtract 3 from both sides to solve the equation.
- **6** Write down both solutions.

Example 6 Solve $2x^2 - 7x + 4 = 0$. Give your solutions in surd form.

$$2x^{2} - 7x + 4 = 0$$

$$2\left(x^{2} - \frac{7}{2}x\right) + 4 = 0$$

$$2\left[\left(x - \frac{7}{4}\right)^{2} - \left(\frac{7}{4}\right)^{2}\right] + 4 = 0$$

$$2\left(x - \frac{7}{4}\right)^{2} - \frac{49}{8} + 4 = 0$$

 $2\left(x-\frac{7}{4}\right)^2-\frac{17}{8}=0$

- 1 Before completing the square write $ax^2 + bx + c$ in the form $a(x^2 + bx) + c$
- 2 Now complete the square by writing $x^2 \frac{7}{2}x$ in the form $\left(x + \frac{b}{2a}\right)^2 \left(\frac{b}{2a}\right)^2$
- 3 Expand the square brackets.
- 4 Simplify.

(continued on next page)

$$2\left(x - \frac{7}{4}\right)^2 = \frac{17}{8}$$

$$\left(x - \frac{7}{4}\right)^2 = \frac{17}{16}$$

$$x - \frac{7}{4} = \pm \frac{\sqrt{17}}{4}$$

$$x = \pm \frac{\sqrt{17}}{4} + \frac{7}{4}$$

So
$$x = \frac{7}{4} - \frac{\sqrt{17}}{4}$$
 or $x = \frac{7}{4} + \frac{\sqrt{17}}{4}$

- 5 Rearrange the equation to work out
 - x. First, add $\frac{17}{8}$ to both sides.
- **6** Divide both sides by 2.
- 7 Square root both sides. Remember that the square root of a value gives two answers.
- 8 Add $\frac{7}{4}$ to both sides.
- **9** Write down both the solutions.

Solving quadratic equations by using the formula

A LEVEL LINKS

Scheme of work: 1b. Quadratic functions – factorising, solving, graphs and the discriminants

Key points

- Any quadratic equation of the form $ax^2 + bx + c = 0$ can be solved using the formula $x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$
- If $b^2 4ac$ is negative then the quadratic equation does not have any real solutions.
- It is useful to write down the formula before substituting the values for a, b and c.

Examples

Example 7 Solve $x^2 + 6x + 4 = 0$. Give your solutions in surd form.

$$a = 1, b = 6, c = 4$$
$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

$$x = \frac{-6 \pm \sqrt{6^2 - 4(1)(4)}}{2(1)}$$
$$x = \frac{-6 \pm \sqrt{20}}{2}$$

$$x = \frac{-6 \pm \sqrt{20}}{2}$$

$$x = \frac{-6 \pm 2\sqrt{5}}{2}$$

$$x = -3 \pm \sqrt{5}$$

So
$$x = -3 - \sqrt{5}$$
 or $x = \sqrt{5} - 3$

1 Identify
$$a$$
, b and c and write down the formula.

Remember that
$$-b \pm \sqrt{b^2 - 4ac}$$
 is all over $2a$, not just part of it.

2 Substitute
$$a = 1$$
, $b = 6$, $c = 4$ into the formula.

3 Simplify. The denominator is 2, but this is only because
$$a = 1$$
. The denominator will not always be 2.

4 Simplify
$$\sqrt{20}$$
.

$$\sqrt{20} = \sqrt{4 \times 5} = \sqrt{4} \times \sqrt{5} = 2\sqrt{5}$$

Example 8 Solve $3x^2 - 7x - 2 = 0$. Give your solutions in surd form.

$$a = 3, b = -7, c = -2$$
$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

$$x = \frac{-(-7) \pm \sqrt{(-7)^2 - 4(3)(-2)}}{2(3)}$$

$$x = \frac{7 \pm \sqrt{73}}{6}$$
So $x = \frac{7 - \sqrt{73}}{6}$ or $x = \frac{7 + \sqrt{73}}{6}$

- 1 Identify *a*, *b* and *c*, making sure you get the signs right and write down the formula.
 - Remember that $-b \pm \sqrt{b^2 4ac}$ is all over 2a, not just part of it.
- 2 Substitute a = 3, b = -7, c = -2 into the formula.
- 3 Simplify. The denominator is 6 when a = 3. A common mistake is to always write a denominator of 2.
- 4 Write down both the solutions.

Solving linear simultaneous equations using the elimination method

A LEVEL LINKS

Scheme of work: 1c. Equations – quadratic/linear simultaneous

Key points

- Two equations are simultaneous when they are both true at the same time.
- Solving simultaneous linear equations in two unknowns involves finding the value of each unknown which works for both equations.
- Make sure that the coefficient of one of the unknowns is the same in both equations.
- Eliminate this equal unknown by either subtracting or adding the two equations.

Examples

Example 1 Solve the simultaneous equations 3x + y = 5 and x + y = 1

3x + y = 5 $- x + y = 1$	
2x = 4	
So $x = 2$	
Using $x + y = 1$	
2 + y = 1 So $y = -1$	
30 y - 1	
Check:	
equation 1: $3 \times 2 + (-1) = 5$	
equation 2: $2 + (-1) = 1$	YES

- 1 Subtract the second equation from the first equation to eliminate the *y* term.
- 2 To find the value of y, substitute x = 2 into one of the original equations.
- 3 Substitute the values of *x* and *y* into both equations to check your answers.

Example 2 Solve x + 2y = 13 and 5x - 2y = 5 simultaneously.

$$x + 2y = 13
+ 5x - 2y = 5
\hline
 6x = 18
So x = 3$$
Using $x + 2y = 13$
 $3 + 2y = 13$
So $y = 5$
Check:

equation 1: $3 + 2 \times 5 = 13$

equation 2: $5 \times 3 - 2 \times 5 = 5$ YES

YES

- 1 Add the two equations together to eliminate the *y* term.
- 2 To find the value of y, substitute x = 3 into one of the original equations.
- **3** Substitute the values of *x* and *y* into both equations to check your answers.

Example 3 Solve 2x + 3y = 2 and 5x + 4y = 12 simultaneously.

$$(2x + 3y = 2) \times 4 \rightarrow 8x + 12y = 8$$

 $(5x + 4y = 12) \times 3 \rightarrow 15x + 12y = 36$
 $7x = 28$

So
$$x = 4$$

Using
$$2x + 3y = 2$$

 $2 \times 4 + 3y = 2$
So $y = -2$

Check:

equation 1:
$$2 \times 4 + 3 \times (-2) = 2$$
 YES
equation 2: $5 \times 4 + 4 \times (-2) = 12$ YES

- 1 Multiply the first equation by 4 and the second equation by 3 to make the coefficient of *y* the same for both equations. Then subtract the first equation from the second equation to eliminate the *y* term.
- 2 To find the value of y, substitute x = 4 into one of the original equations.
- 3 Substitute the values of *x* and *y* into both equations to check your answers.

Practice

Solve these simultaneous equations.

$$\begin{aligned}
\mathbf{1} & 4x + y = 8 \\
x + y &= 5
\end{aligned}$$

$$3x + y = 7 3x + 2y = 5$$

$$3 4x + y = 3$$
$$3x - y = 11$$

$$4 3x + 4y = 7$$
$$x - 4y = 5$$

$$5 2x + y = 11$$
$$x - 3y = 9$$

$$6 \qquad 2x + 3y = 11$$
$$3x + 2y = 4$$

Solving linear simultaneous equations using the substitution method

A LEVEL LINKS: Scheme of work: 1c. Equations – quadratic/linear simultaneous

Key points

• The substitution method is the method most commonly used for A level. This is because it is the method used to solve linear and quadratic simultaneous equations.

Examples

Example 4 Solve the simultaneous equations y = 2x + 1 and 5x + 3y = 14

$$5x + 3(2x + 1) = 14$$

$$5x + 6x + 3 = 14$$

$$11x + 3 = 14$$

$$11x = 11$$
So $x = 1$
Using $y = 2x + 1$

$$y = 2 \times 1 + 1$$
So $y = 3$
Check:
equation 1: $3 = 2 \times 1 + 1$ YES
equation 2: $5 \times 1 + 3 \times 3 = 14$ YES

- 1 Substitute 2x + 1 for y into the second equation.
- **2** Expand the brackets and simplify.
- 3 Work out the value of x.
- **4** To find the value of *y*, substitute x = 1 into one of the original equations.
- 5 Substitute the values of *x* and *y* into both equations to check your answers.

Example 5 Solve 2x - y = 16 and 4x + 3y = -3 simultaneously.

$$y = 2x - 16$$

$$4x + 3(2x - 16) = -3$$

$$4x + 6x - 48 = -3$$

$$10x - 48 = -3$$

$$10x = 45$$
So $x = 4\frac{1}{2}$
Using $y = 2x - 16$

$$y = 2 \times 4\frac{1}{2} - 16$$
So $y = -7$
Check:
equation 1: $2 \times 4\frac{1}{2} - (-7) = 16$
YES
equation 2: $4 \times 4\frac{1}{2} + 3 \times (-7) = -3$

YES

- **1** Rearrange the first equation.
- 2 Substitute 2x 16 for y into the second equation.
- 3 Expand the brackets and simplify.
- 4 Work out the value of x.
- 5 To find the value of y, substitute $x = 4\frac{1}{2}$ into one of the original equations.
- 6 Substitute the values of x and y into both equations to check your answers.

Solve these simultaneous equations.

7
$$y = x - 4$$

$$2x + 5y = 43$$

9
$$2y = 4x + 5$$

$$9x + 5y = 22$$

11
$$3x + 4y = 8$$

$$2x - y = -13$$

13
$$3x = y - 1$$

$$2y - 2x = 3$$

8
$$y = 2x - 3$$

 $5x - 3y = 11$

10
$$2x = y - 2$$

$$8x - 5y = -11$$

12
$$3y = 4x - 7$$

$$2y = 3x - 4$$

14
$$3x + 2y + 1 = 0$$

$$4y = 8 - x$$
